• Brain tumors (BT) are one of the most frequent types of cancer in children.

• Childhood BT survivors have different problems and notable QoL impairment due to impact of both the cancer and antitumor treatment.

• Parents and siblings of BT survivors are confronted with major changes and burden in their lives.

• Family-oriented rehabilitation is promising to support cancer children and their families with the re-entry into ‘normal’ life.

• The main goal of rehabilitation in cancer survivors – to improve/maintain QoL.

• We aimed to evaluate QoL in children with BT in remission and their parents during family-oriented rehabilitation.
PATIENTS AND METHODS

Clinical Rehabilitation Research Center for children with oncological, hematological and immunological diseases "Russkoye pole“

- **Children** are undergoing a 4-weeks complex medical social rehabilitation program after the end of cancer treatment, which includes:
  - correction of stato-kinetic disorders
  - medical-physical rehabilitation
  - neuro-psychological correction
  - psychological support
  - educational assistance
  - social support
- **Parents** are having the following types of support:
  - psychological support
  - social support
  - social-legal consultation
PATIENTS AND METHODS

Sample characteristics

</table>

BT types in survivors: medulloblastoma (49%), astrocytoma (22%), anaplastic ependymoma (4%), others (25%)

QoL questionnaires
- PedsQL – QoL assessment in children (child- and parent-report forms)
- RAND SF-36 – QoL assessment in parents

Time points for QoL assessment
First evaluation - before rehabilitation,
Second evaluation - after rehabilitation

QoL in children before and after rehabilitation by child-reports

**RESULTS**

**PedsQL scales:**
- PF – physical functioning,
- EF – emotional functioning,
- SF – social functioning,
- SchF – school functioning;
- PSF – psychosocial functioning,
- Total Scale Score

*• According to child-reports QoL increased mainly in terms of *emotional* (64.1 vs 72.0) and *social functioning* (68.5 vs 74.8).
• **Psychosocial functioning** and **Total Scale Score** significantly increased (63.6 vs 69.8, 62.4 vs 68.1).
• QoL improvement was revealed in children with adjustment for age, gender, duration of remission and baseline QoL (p<.05).*
RESULTS

QoL in children before and after rehabilitation by parent-reports

- According to parent-reports QoL in children increased mainly in terms of social functioning (60.1 vs 67.6).
- **Psychosocial functioning** and **Total Scale Score** significantly increased (57.1 vs 62.0, 53.8 vs 58.0).

PedsQL scales:
- PF – physical functioning,
- EF – emotional functioning,
- SF – social functioning,
- SchF – school functioning;

**PSF – psychosocial functioning, Total Scale Score**

QoL in parents before and after rehabilitation

- Parents’ QoL improved almost by all SF-36 scales with adjustment for their age, gender, baseline QoL and duration of remission in children (p<.05).
RESULTS

Distribution of BT survivors according to QoL changes after rehabilitation as compared to healthy peers

- QoL improved in 24% of BT survivors.
- QoL was stable in 73% of BT survivors.
- QoL deteriorated in 3% of BT survivors.

- After rehabilitation, the number of BT survivors with significant QoL impairment decreased (78% vs 57%, p<.001).
RESULTS

Distribution of BT survivors according to QoL changes after rehabilitation as compared with baseline by Total Scale Score

- QoL improved in 58% of BT survivors.
- QoL was stable in 21% of BT survivors.
- QoL deteriorated in 21% of BT survivors.
CONCLUSIONS

- Family-oriented rehabilitation is effective in terms of QoL improvement both in surviving children with brain tumors and in their parents.
- QoL information may help to identify specific support needs for cancer survivors and their families.
- Taking into account the revealed heterogeneity of surviving children in terms of QoL changes, further ongoing work is worthwhile to identify predictors of QoL changes during rehabilitation.
